

Cost and success do not move together: every cell has several non-dominated modes, and several dominated ones

Filled outlines are non-dominated (1-3 per cell); faded points cost more AND succeed less than some alternative, and are shown rather than hidden. Cost is summed over the episode's ACTUAL steps, not inferred from a per-step context length — which is why a weaker mode can be the more expensive one (it spends the step budget failing). Panels use separate axes on purpose: both are total_billed_cost_usd, but B0's per-1k schedule is a vendor price and B1/B2's a device-amortisation rate, and the two are never divided by one another.

Source: docs/analysis/cross_sites/router_objective_ordering.md (cost = total_billed_cost_usd, the canonical estimand — token-priced throughout, NOT measured energy), cross-checked against sr_per_mode.json for the six VWA cells; the two WA cells are single-source.
