

Three ways out of the label shortage — and three different reasons none of them works

Labels for the which-mode router exist only where some mode succeeded: 15-97 per cell, 260 pooled over six cells, and 4 of 6 cells with no trainable classifier at all. If the shortage were a slicing problem one of these routes would relieve it. Each fails in a structurally different way, which is the argument that the constraint is a production rate rather than a labelling choice.
