

Cost and success do not move together: every cell has several non-dominated modes, and several dominated ones

Filled outlines are non-dominated (1-3 per cell); faded points cost more AND succeed less than some alternative, and are shown rather than hidden. Cost is measured per episode, not assumed from a token schedule — which is why a weaker mode can be the more expensive one (it spends the step budget failing). Panels use separate axes on purpose: B0 is billed API dollars, B1/B2 an electricity equivalent from device telemetry, and the two are never divided by one another.
