

With the labels destroyed, the sweep still finds most of the saving in 2 of 8 cells

Grey = what a signal-free pipeline reproduces. 1 of 8 cells survive Holm at $\alpha=0.05$. Surviving the null is necessary, not sufficient: it says the saving is not an artefact of the sweep, not that the policy is worth deploying — for that comparison see F13.

B=10,000 permutations per cell; unit is the whole task bundle (y, succ, cost) against X, not y alone. p is the plus-one estimator $(k+1)/(B+1)$. Holm computed over the $m=8$ cells present.
